

## Chapter 2

### Evolution of the Major Programming Languages

---

---

---

---

---

---

---

---

### Chapter 2 Topics

1. Zuse's Plankalkul
2. Minimal Hardware Programming: Pseudocodes
3. The IBM 704 and Fortran
4. Functional Programming: LISP
5. The First Step Toward Sophistication: ALGOL 60
6. Computerizing Business Records: COBOL
7. The Beginnings of Timesharing: BASIC

2-2

---

---

---

---

---

---

---

---

### Chapter 2 Topics (continued)

8. Everything for Everybody: PL/I
9. Two Early Dynamic Languages: APL and SNOBOL
10. The Beginnings of Data Abstraction: SIMULA 67
11. Orthogonal Design: ALGOL 68
12. Some Early Descendants of the ALGOLs
13. Programming Based on Logic: Prolog
14. History's Largest Design Effort: Ada

2-3

---

---

---

---

---

---

---

---

## Chapter 3 Topics

---

1. Introduction
2. The General Problem of Describing Syntax
3. Formal Methods of Describing Syntax
4. Attribute Grammars
5. Describing the Meanings of Programs:  
Dynamic Semantics

Copyright © 2006 Pearson Addison-Wesley. All rights reserved.

2-7

---

---

---

---

---

---

---

---

## 3.1 Introduction

---

- **Syntax:** the form or structure of the expressions, statements, and program units
- **Semantics:** the meaning of the expressions, statements, and program units
- Syntax and semantics provide a language's definition
  - Users of a language definition
    - Other language designers
    - Implementers
    - Programmers (the users of the language)

2-8

---

---

---

---

---

---

---

---

## 3.2 The General Problem of Describing Syntax: Terminology

---

- A *sentence* is a string of characters over some alphabet
- A *language* is a set of sentences
- A *lexeme* is the lowest level syntactic unit of a language (e.g., \*, sum, begin)
- A *token* is a category of lexemes (e.g., identifier)

2-9

---

---

---

---

---

---

---

---

## Formal Definition of Languages

- **Recognizers**

- A recognition device reads input strings of the language and decides whether the input strings belong to the language
- Example: syntax analysis part of a compiler
- Detailed discussion in Chapter 4

- **Generators**

- A device that generates sentences of a language
- One can determine if the syntax of a particular sentence is correct by comparing it to the structure of the generator

2-10

---

---

---

---

---

---

---

---

## 3.3 Formal Methods of Describing Syntax

- **Backus-Naur Form and Context-Free Grammars**

- Most widely known method for describing programming language syntax

- **Extended BNF**

- Improves readability and writability of BNF

- **Grammars and Recognizers**

2-11

---

---

---

---

---

---

---

---

## Chapter 4 Topics

1. Introduction
2. Lexical Analysis
3. The Parsing Problem
4. Recursive-Descent Parsing
5. Bottom-Up Parsing

Copyright © 2006 Pearson Addison-Wesley. All rights reserved.

2-12

---

---

---

---

---

---

---

---

## 4.1 Introduction

---

- The syntax analysis portion of a language processor nearly always consists of two parts:
  - A low-level part called a *lexical analyzer* (mathematically, a finite automaton based on a regular grammar)
  - A high-level part called a *syntax analyzer*, or parser (mathematically, a push-down automaton based on a context-free grammar, or BNF)

2-13

---

---

---

---

---

---

---

---

## 4.1 Introduction (cont.)

---

- Reasons to use BNF to describe syntax:
  - Provides a clear and concise syntax description
  - The parser can be based directly on the BNF
  - Parsers based on BNF are easy to maintain

Copyright © 2006 Pearson Addison-Wesley. All rights reserved.

2-14

---

---

---

---

---

---

---

---

## 4.1 Introduction (cont.)

---

- Reasons to separate lexical and syntax analysis:
  - **Simplicity** – less complex approaches can be used for lexical analysis; separating them simplifies the parser
  - **Efficiency** – separation allows optimization of the lexical analyzer
  - **Portability** – parts of the lexical analyzer may not be portable, but the parser always is portable

2-15

---

---

---

---

---

---

---

---

## 4.2 Lexical Analysis

- A lexical analyzer is a pattern matcher for character strings
- A lexical analyzer is a “front-end” for the parser
- Identifies substrings of the source program that belong together – **lexemes**
  - Lexemes match a character pattern, which is associated with a lexical category called a **token**
  - **sum** is a lexeme; its token may be **IDENT**

2-16

---

---

---

---

---

---

---

---

## 4.2 Lexical Analysis (cont.)

- The lexical analyzer is usually a function that is called by the parser when it needs the next token
- Three approaches to building a lexical analyzer:
  - Write a formal description of the tokens and use a software tool that constructs table-driven lexical analyzers given such a description
  - Design a state diagram that describes the tokens and write a program that implements the state diagram
  - Design a state diagram that describes the tokens and hand-construct a table-driven implementation of the state diagram
- book only discusses approach 2

2-17

---

---

---

---

---

---

---

---

## Lexical Analysis

- Using Finite State Machines to implement lexical scan
- **Example:** Design a FSM which translates input text line by line so that the following rule is followed correcting spelling mistakes wrt “ei” and “cei”: “*j* should be followed by *e* except when immediately followed by *c*”.
- **Input:** She will eat a pie if there is a pei and when she recieves it.
- **Output:** She will eat a pie if there is a pie and when she receives it.

2-18

---

---

---

---

---

---

---

---

## 4.2 Lexical Analysis (cont.)

- State diagram design:
  - A naïve state diagram would have a transition from every state on every character in the source language – such a diagram would be very large!

Copyright © 2006 Pearson Addison-Wesley. All rights reserved.

2-19

---

---

---

---

---

---

---

---

## 4.2 Lexical Analysis (cont.)

- In many cases, transitions can be combined to simplify the state diagram
  - When recognizing an identifier, all uppercase and lowercase letters are equivalent
    - Use a *character class* that includes all letters
  - When recognizing an integer literal, all digits are equivalent – use a *digit class*

Copyright © 2006 Pearson Addison-Wesley. All rights reserved.

2-20

---

---

---

---

---

---

---

---

## 4.2 Lexical Analysis (cont.)

- Reserved words and identifiers can be recognized together (rather than having a part of the diagram for each reserved word)
  - Use a table lookup to determine whether a possible identifier is in fact a reserved word

Copyright © 2006 Pearson Addison-Wesley. All rights reserved.

2-21

---

---

---

---

---

---

---

---

## 4.2 Lexical Analysis (cont.)

- Convenient utility subprograms:
  - `getChar` - gets the next character of input, puts it in `nextChar`, determines its class and puts the class in `charClass`
  - `addChar` - puts the character from `nextChar` into the place the lexeme is being accumulated, `lexeme`
  - `lookup` - determines whether the string in `lexeme` is a reserved word (returns a code)

2-23

---

---

---

---

---

---

---

---

## 4.2 Lexical Analysis (cont.)

Implementation (assume initialization):

```
int lex() {  
    getChar();  
    switch (charClass) {  
        case LETTER:  
            addChar();  
            getChar();  
            while (charClass == LETTER || charClass == DIGIT)  
            {  
                addChar();  
                getChar();  
            }  
            return lookup(lexeme);  
            break;  
        ...  
    }
```

2-24

---

---

---

---

---

---

---

---

## 4.2 Lexical Analysis (cont.)

---

```
...
case DIGIT:
    addChar();
    getChar();
    while (charClass == DIGIT) {
        addChar();
        getChar();
    }
    return INT_LIT;
    break;
} /* End of switch */
} /* End of function lex */
```

---

---

---

---

---

---

---

---

## HW problems for practice on FSMs

---

- Design a FSM that translates text in which properly delimited *the* is replaced by *a*.
- Design a FSM to strip out comments from a C or C++ program.
- Design a FSM to recognize identifiers in C.
